Lifetime Impact of Congenital Heart Disease on a Family from the Perspective of a Third in Birth Order Sibling

Keywords: Siblings; Congenital heart disease; Acute and chronic health care; Nursing profession; Compassion fatigue

Abstract

Background: Congenital heart disease (CHD) is the number one birth defect reported by the Centers for Disease Control and Prevention [1]. Patients are surviving and thriving into teen and adult years. The evolution of care since the late 1960’s for patients and families include routine and unexpected clinic visits, hospitalizations, and procedures. Transitions into acute care systems and subsequent return to chronic care systems are part of this process. This care is required in addition to normal routine health surveillance and illnesses impacting patients, families, resources, and support systems.

Recognition of the healthy sibling impact and relationship with chronic health disease is present in the literature with inconsistent results across many diseases. The quality of life literature in CHD is progressing through the years, particularly for patients; however, lifetime healthy sibling impact of CHD continues to be void in the literature. Sibling relationships span the longest time period in a lifetime, typically longer than parents and spouses [2]. Focus on sibling impact of chronic illness is essential to understanding the family dynamics, sibling relationships, roles, and family coping mechanisms when faced with a life-threatening illness like CHD.

Method: A Midwestern nuclear intact family is the focus in this case study. In 1968, an infant, second in birth order of 4 siblings, was postnatally diagnosed with complex univentricular CHD requiring repeat surgical and medical follow up throughout his lifetime. This single family review retrospectively spans over four and a half decades. The family review is from the perspective of third in birth order sibling. Utilizing interviews and personal accounts, a developmental perspective of the impact growing up with an ill sibling throughout childhood and adulthood is reported.

Results: Normal developmental milestones of adulthood were achieved by all four siblings including; graduating high school, moving out of the home, marrying, childrearing, and pursuing productive careers. Divorce was not present in the nuclear family and respective adult families. Three of the four siblings graduated with a college degree and a first for our generation.

Conclusion: CHD and the acute life threatening issues associated with surgical and medical follow up impacts the family system. Compassion and empathy evolved throughout the lifespan for one sibling. Exposure to emotional, mental, and physical stressors while providing quality health care can be significant. The development of professional compassion fatigue [3] and nursing burnout in the third in birth order sibling was identified.

Family resilience was critical to positively moving forward. Eight positive resilience factors were identified as key to maintain a positive focus and live life to the fullest capacity. These included: consistent positive family support, spiritual support, family financial stability, quality health care, strong work ethic, presence of humor, focus on quality of life and normalcy, and drive for adventure and new experiences.

Introduction

Congenital heart disease (CHD) is the most common birth defect occurring 1 in 100 births or 1.2 million babies worldwide annually. Severe CHD occurs in 1 in 300 births or approximately 340,000 worldwide [4]. The management of CHD has rapidly progressed since introduction of pediatric cardiopulmonary bypass and advances in the medical, surgical, and nursing care has enabled “blue babies” to not only survive childhood but successfully transition to adulthood [5]. Consequently, meeting the needs of complex CHD and their families requires exploring best practices, practical resource utilization, and continual care throughout a lifetime [6].

Family impact in the literature can be traced back to a study of 100 randomly selected children on infant wards. This study explored the impact of CHD on the family and at risk families, particularly “overreacting” and "generally immature” parents [7]. Empathy is assessed on healthy young siblings associated with CHD in one small sample study of 28 siblings [8]. With severe CHD, like my brother’s, a relationship to anxiety and depression is suggested in the literature [9]. In recent years, the quality of life literature demonstrates a lower health related quality of life of children and adolescents with biventricular and single ventricular CHD [10].

Qualitative research by Rempel and Harrison in 2007 identifies the need for parents to safeguard the precarious survival of the child and safeguard the precarious survival of self (and the couple) when faced with a complex single ventricle disease called hypoplastic left heart syndrome (HLHs) [11]. Rempel also identifies grandparents stepping in and helping with care of daily routines, play, and recreation. The double concern for their children and ill grandchildren, and added sibling care roles creates a triple concern for grandparents [12].

Anxiety disorders in children and adolescents are among the most common and functionally impairing mental health disorders to occur in childhood and adolescence with an increased risk for future anxiety sparking the need for identification by primary care providers.
[13]. The study by Stewart in 1991 describes the need of siblings to be able to talk with doctors (and other health professionals) about the illness of their sibling [14]. Inconsistent results are present in the literature regarding the well sibling and impact of chronic health disease with medical diagnosis predominantly outside of CHD and in small convenient sample sizes [15-17].

Feary in 2013 identifies the need for further sibling research growing up with chronic health issues and highlights the emphasis a heavy focus in the oncology population. A targeted study using college students looked at questions such as: “Looking back, what would you want to happen differently about the experience?” What were your biggest fears then?” “How has the disease affected your life?” “How about now, do you have any fears or worries that stem from your sibling’s illness?” [18]. Jewsbury Conger, described the milestones of leaving home, completing education, employment, marriage, childbearing, and moving out and moving on with new roles and new relationships as milestones of adulthood [19].

In 2015, Humphrey focused on psychosocial well beings of siblings of children with life-threatening illness with the diagnosis ranging from neuromuscular (30%), genetic/congenital (27%), cardiovascular (17%), metabolic (10%), oncological (10%), and respiratory (7%). No lower psychological well-being than the general population was the outcome found and supported their prediction of presence of a positive family environment would be associated with higher levels of psychological health. This sample size was small including 24 parents and 30 siblings and also consisted of mostly Caucasian, two-parent households, and only minor financial concerns [20]. Building resilience in young children and teens throughout growth and development is essential. Ginsburg and Jablow in their book published in 2015 identified chronic disease may bring limitations and impact a child’s capabilities but does not prevent children from becoming resilient [21].

Introduction to the Case Study

CHD met our nuclear family in a small Midwest town in 1968 while the family was still growing. My parents, grandparents, family, and friends had no awareness of what CHD was or the impact. By the time I was born in 1970, the second born sibling was already showing the health care providers that he was a survivor of complex univentricular disease. It occurs in less than 1% of CHD with a high mortality up to 50% in infancy [22]. He wasn’t expected to make it to his second birthday, just one month away. He did live, grow, and moved on to a surgical procedure in order to provide more pulmonary blood flow to facilitate further growth and development.

Complex univentricular CHD was such a foreign topic to the family. The anatomy and surgical interventions are listed below in Table 1. Grasping the enormity of the issues is challenging and can be very overwhelming without proper health provider guidance. In the 1960’s, the technology was not present to reliably and responsibly predict any outcomes. “The future is unknown” and “we are embarking on uncharted territory” were common conversations within our household and medical offices.

Any one of these diagnosis labeled in Table 1 can be difficult to process in isolation and impact on health. Imagine to yourself how you describe this diagnosis to any lay person, parent, sibling, or family member. How do you pronounce these large medical terms much less define them? What does it mean clinically? In our family, it became known that there was a “very rare single ventricle disease” present that required unusual reorganization of my brother’s cardiac “plumbing” to keep blood flowing well to the body and all essential organs to sustain life.

Despite the complex diagnosis, CHD in my family was a fairly invisible disease of childhood to those outside looking into our family. Other than the surgical incisions in 1970 and 1985 and some activity intolerance, my brother looked and acted like any other child his age.

Extended family and parents

In this working middle class family’s experience with CHD, many supportive family members were present on the journey. Parents, now 70 and 69 years of age, were born and raised with large Catholic families consisting of 11 siblings and 6 siblings, respectively. Birth order was paternal (third youngest) and maternal (third eldest). Maternal and paternal grandparents modeled families where the father was the main breadwinner. Common to the times, most maternal and paternal siblings resided within a few mile radius of the small Midwestern town. Homebuilding and paper mill work were common careers in both families. Persistence and perseverance no matter what the task at hand were family strengths of parents and grandparents. Paternal family history of depression requiring treatment was present.

My parents married and started a family shortly after graduation. As the main breadwinner, my father worked as a master electrician in the paper mills on swing shift which meant rotating all three shifts to provide for the family. He also started his own electrical contracting business. Paternal depression, anxiety, over-eating, and alcoholism were present. Functioning as homemaker and main caregiver, my mother also supported the growing family electrical contracting business run out of the home. All four children were expected to join the workforce in the family business throughout childhood at an age appropriate developmental level to learn a strong work ethic. The opportunity for a well-paying summer employment was available at my father’s paper mill for all college students as part of work benefits.

Food, clothing, and shelter were secured by practical means with inexpensive purchases and extensive use of hand me down clothing. Lack of extra funds for playtime activities didn’t limit parental thriftiness and exposure to amazing new experiences in life. One example of this is a family purchase. Every child contributed $200 to purchase an old tri-hull roundabout boat and motor for water sports. Many times, we had three of us in tow behind the boat, including my mother who was instrumental in helping so many people learn to ski. Together the family restored, painted, and maintained the boat.

Aunts, uncles, and older cousins were babysitters for the family to provide my parents adult only time or support the activity needs of the household. My mother’s best friend from high school lived in the neighboring town. She was a professional beautician, unmarried, without children, and a great support resource close to our family. On occasions when my parents were out of town for a night or extended overnights, such as in 1985 for the Fontan operation, she provided.

**Case study**

In 1968, cell phones, internet, and technology gadgets to stay connected were not invented. My mother gave birth to a term son, second in birth order, at the age of twenty-three. My parents and eldest brother, then 1-year-old, were living in a duplex making plans to build a new home. My uncle and godparents lived right next door to us and were also beginning their young family. After postnatal diagnosis of a significant cardiac health concern, my brother was promptly transferred via ambulance accompanied by my father to the local children’s hospital in the state. The local hospital was two hours travel time by car with a growing pediatric cardiovascular program.

The ambulance ride was the beginning of many family trips to Milwaukee. At that time, there was no emergency room or intensive care unit. The chief of pediatric cardiology took on my brother’s case to evaluate the nature of his cardiac disease and began a longstanding and trusting relationship. Multiple family members assisted with travel to and from the hospital during this hospital stay. Upon discharge, my parents bought a baby scale and mother weighed him and diligently tracked intake, output, and weights in a green notebook. My mother would bring this evidence in to share with the cardiologist at follow up visits (Figures 1 and 2).

In 1970 a practicing general surgeon also certified in thoracic surgery, performed a Blalock-Taussig Shunt for my brother and was discharged 3 weeks later with a healing full thoracotomy. Limited open sleeping space available in the hospital hallways was utilized by my parents. They took turns traveling back and forth supporting the family back home and recovering second born son’s needs.

A dedicated pediatric cardiovascular surgery team for CHD was in place in Milwaukee and growing with a formal pediatric surgical CHD program starting in 1973 when Dr. Bert Litwin joined the practice. Diligent follow-up continued with the chief of cardiology and so did focus on normal life events. In 1973, my parents welcomed the last of their four children into the world and were settling into their newly built dream home. It was designed and built with their hands just one town line away.

**Description of childhood**

Breastfeeding was attempted in the first two children but ceased due to ankyloglossia, (tongue tie) and CHD respectively. All recommendations for immunizations were followed. An outbreak of chicken pox was shared as young children. No significant chronic health issues outside of environmental allergies were present. Unexpected visits to the doctor and emergency rooms for ear infections, other childhood illnesses, stitches, and broken bones were encountered.

Three elementary schools filtered into one middle school and one high school. Living with CHD was unknown to most. Conversations and education with the school nurse about CHD did not occur on any regular basis or at all. In fact, my mother couldn’t recall who the school nurse was growing up. The school nurse had a long time dedication in the school system according to a local pharmacist who worked with her on numerous occasions advocating for the health and well-being of disadvantage children in the school system. She is described as, “having a personality looking through eye glasses…champion of causes to normalize children in relationship to peers with a calm, collective, reassuring, and humorous nature.”

A physical education teacher within the high school lived next door to our family. As a teacher and parent, he had an opportunity to observe my brother in gym class and being a child playing around the neighborhood. No pulse oximeters were accessible at home or school. There were times he was visibly quite blue or cyanotic with exertion. On one occasion at school, my older brother stepped up to defend my brother who was being bullied because of his cyanosis. Through the years, my brother was charged with learning and being aware of his capabilities and fatigue during any gym class and any activities that were physical exertion was in question. Study hall was always an option if needed.

Sidewalks were prevalent in our small Midwestern town and typical free play activities of childhood were encouraged outside until dark, weather permitting. Bike riding, walking, daily trips to the local swimming pool for lessons and open swim, and local pick-up games in the neighboring vacant grass lot were common events. Weekly piano lessons were encouraged for all children in the family. My mother even took a few lessons. Building forts, creating homemade go carts, playing kick the can, and performing neighborhood plays were fond memories of childhood. Indoor activities were board games and an Atari game system. As a congregation corner house in the neighborhood, friends and cousins were encouraged to play, hang out, and have sleepovers. Humor, laughter, and full out belly laughs were common, particularly when used with competition between sibling activities. Learning to water ski, kneeboard, parasail, and taking part in the activities on our simple round about boat were family fun times of learning. My parents were new to boating, learned with us, and entrusted us to engage in opportunities to take the boat out as teens once we accomplished driving and boat safety.

Helicopter parenting or overprotecting mothers and fathers with excessive interest in their children’s activities was simply not an option in our family because my parents could not be present for all open and unstructured free time. Working two jobs, my father had little time left in the day. Play dates were not organized for us by our mother. We played with whoever was around making...
sure we respected my father’s time to sleep based on his swing shift schedule. Family members and cousins were plentiful for playmates and support. Running a household, providing a safe environment, performing personal business chores and accounting, volunteering as a den mother for cub scouts, and organizing memorable and simple birthday celebration parties kept my mother very busy.

Day trip family outings throughout the state and neighboring states included local parks, zoos, theme parks, and lakes. Annually at a minimum, a traditional day long trip to Great America was an essential destination. We would arrive at 10 am and leave at 10 pm to get the most value out of our day long ticket running from coaster to coaster. As kids, we often promptly fell asleep as soon as we got in the car for the 3 hour drive home. Follow up visits in Milwaukee were often tied into family outings. Over time, these outings were based on health status. If all was going well, they were spread out to annually. Annual vacations up north at various rental cottages were rituals often shared with uncles, aunts, and cousins close in age to our family. Options to bring a friend along were often part of the planning as we grew older.

Expectations of family life

Family expectations to provide quality medical support, insurance, and quality of life for all four siblings remained the utmost focus. My father navigated this consistently by working in a paper mill on swing shift, signing up for overtime and extra shifts, running his electrical contracting business, and maintaining health benefits with the local paper company.

Expectations within the household for routine chores, education, and music experience were consistent among all four siblings. No allowances were provided. Anything above and beyond routine safety, food, shelter, and clothing was provided by our own funds. Educational tutors were provided during prolonged hospitalizations to keep up with current class work. In our early and late teen years, independence and responsibility grew. In addition to learning driver’s safety, expectations to obtain boater and motorcycle safety courses at the local technical college were added.

Holiday gift giving by parents was consistent to the dollar amount for each child. My mother made certain not to demonstrate any favoritism. Typical sibling rivalry was present, particularly between the second and third born. Powerful themes of continued education and learning throughout a lifetime, proper prior planning, fostering independence, and striving for the best with whatever you do or encounter in life were expected and discussed throughout childhood. The locus of control modeled in the family was internally focused with empathy and compassion modeled.

Perspective growing up from a sister and future nurse

One “aha” or “lightbulb” moment in my anatomy and physiology class occurred in 9th grade when we discussed the heart and all its components. While providing some clarity, it was still difficult to
understand his diagnosis and how it related to what I saw clinically in my brother. CHD was fairly invisible to my eyes as a child just like others who looked into our family. His first surgery occurred when I was three months old; thus, no memory of the event. To me, he kept up with all of us as siblings and sported a large healed thoracotomy incision as a battle wound of early childhood. While thinner, bluer lips, and different shape to his nail beds, he demonstrated flexibility with muscle and ligaments and skills in math and puzzle solving. Competitive sports were discouraged by the health team; however, he didn’t shy from activity and learned how to waterski, kneeborder, parasail, and navigate the sailboat and sailboard with ease. He could ride the unicycle all over town. In my eyes, he never appeared to be a sick child until he broke his arm with an open fracture at the elementary playground falling from a dome landing in traction at the local hospital for many weeks (Figures 3 and 4).

While in high school, the decision was made by the medical team and my parents that it was time to have a Fontan procedure to help with his cyanosis and restricted blood flow. This surgery wasn’t even an option when my brother was born but was now a reasonable treatment option. When it came time for his surgery in 1985, he was referred to a world renowned center of excellence with more specialists, and social workers trained to facilitate families through the process of a hospitalization. The cardiologists and experts and providers such as: nursing educators, practitioners, child life specialist, and social workers trained to facilitate families through the process of a hospitalization.

The decision for surgery moved CHD in the foreground again from his place of normalcy. My parents navigated the insurance coverage, lodging, and preparations to support our entire family system. This time period is when the unknown and mystery of CHD really sparked my interest. I had no idea what to expect when my brother went off to the hospital and honestly wanted my parent’s attention too. The local community hospital was only 10 miles away from home. A visit, play, sharing treats, and go returning home in the same day were easy. The hospital this time was 250 miles away and difficult task.

Aware that my parents were stressed, I continued to wear my “good child” hat to do what was needed when extra chores were asked of me. Circling in my mind were countless questions and no real answers. What would it be like? What would be done? Would he die? Would he be in pain? Can I visit? Can I call? Why does he get all the attention? What are the expectations and length of hospital stay? How would this impact our family? How would the rest of us keep going?

My parents had a lot of these questions too and trusted their child’s pediatric cardiologist to continue guiding and reassuring just as he did in 1968, 1970, and at every follow-up visit. Providing a more balanced circulation was the target for a better quality of life. Research and surgical techniques progressed in the decades up to 1985, but there was still many unknowns and uncertainties for patients and family's journey with CHD into adulthood. The Fontan procedure was a major operation with risks of significant potential complications, including death.

The first few weeks, he was very ill and puffy but had “pink” lips and nail beds per my parents report. I never visited while he was hospitalized and never had the courage to ask for an opportunity trying not to disrupt the flow in the family. After four weeks, discharge home with a healing full sternotomy and multiple chest tube sites as his “bragging rights” and evidence of his hospital course (Figure 5). As I grew older into adulthood, the postoperative significance of persistent chest tube drainage became clearer and remains a very real complication issue extending length of hospitalizations. Persistent chest tube drainage and hospitalization in the “chest tube hotel,” as my family describes it, was the only significant complication. Similar to the hospitalization as a young teen for the fracture, tutors and educational support continued throughout the recovery process to maintain education as a primary focus of growth and development.

In retrospect, many fears and mystery surrounding my brother’s hospitalization were present. I had no concept of what a chest tube was or what it meant to be hospitalized after open heart surgery. My parents spoke of “drainage tubes” but what was that? As a visual learner, I suspect my fears and anxieties could have been reassured with a thoughtful health care provider and physical presence at the bedside. Today, there are many more educational resources and providers such as: nursing educators, practitioners, child life specialists, and social workers trained to facilitate families through the process of a hospitalization.

As I grew older, I required more in depth answers to my questions and was still puzzled with my still very primitive understanding of a complex disease process and anatomy. The cardiologists and experts...
like my brother became my guide to understanding. My brother often down played things and took the approach like “It’s no big deal” when it came time to describing CHD and approach to impact on him which is very similar to findings in the literature by Shearer in 2013 [23]. My brother was always open to sharing information, promoting research in CHD, and talked about how he felt like a “guinea pig” as one of the oldest single ventricle survivors. At times, there were many residents and fellows standing in line to meet, listen, and examine him. As questions were answered, I learned more and came up with even more questions.

I recall clearly a moment in 1993 practicing as a new graduate nurse on the oncology and transplant floor. While working a shift at the hospital, my brother was having a cardiac catheterization on a different floor. Taking a break from patient care, I stopped by to see him before the procedure to be with him. His long time primary cardiologist had retired and case had been transitioned to a new chief of pediatric cardiology.

Separated by college life for a few years, I saw my brother sitting on the gurney with hospital gown on and bare feet with more clinical eyes. I saw brown spots or evidence of venous stasis bilaterally up to his mid shin. As a nurse became very concerned and made sure the cardiologist was also aware of my concern. Learning about congestive heart failure (CHF) in school and caring for adult patients in my nursing practicums with CHF raised many red flags in my eyes. This period of time was the first moment I realized that my brother’s heart was not functioning as well as everyone would like and the uncertainty of his future was unknown. Tears were shed on the way home from work that day.

The risk associated with CHD increased with age and continued to be present throughout adult life including: arrhythmias, ventricular function, and thrombus that required medical and surgical interventions. Another acute event would surface, and the face of CHD would again take priority in forcing an action management plan to return to a baseline chronic health management state (Figure 6). These unpredictable and predictable transitions are an often natural occurrence in CHD and impact every family member (patient, parent, sibling, grandparent, and beyond).

The natural milestones of my young adult life include: daughter, sibling, wife, mother, aunt, godmother, and nurse practitioner. As time went by, there were many milestones of adulthood shared with my brother and family. As his health failed, the anxiety, fear, and worry about his quality of life and survival grew. Having solid mentors and health care leaders within CHD to talk through these risks and benefits openly and honestly at every step of the way helped immensely to solidify the reality of the situation for me as a sibling and nurse.

Looking back, his last year of life waiting for transplant was the most difficult to deal with as a nurse. Knowing the exact moment by moment congestive heart failure plan of care and last echocardiogram finding would not change the outcome. What would that get me other than more anxiety and fear of the unknown? While my brother has always been very transparent about his care plan with his sister, this was not the time. Being cared for by a center of excellence was reassuring and aided in the process of letting go of my inherent evidence based practice thinking. The priceless moments as a sister were more important to preserve. From my perspective, he was still attached to an intravenous line unable to return home.

As hard as it was to let go of the medical, I did. Focusing on being the best sister I could was primary. Regular visits were scheduled and overnights at the local hotel. They were not vacations by any normal definition of family holidays, but we made them fun connections, laughing whenever we could. Adventures within the walls of the hospital grounds were many: playing some “sour” notes of his favorite Billy Joel songs on the piano, attending a local conference, bringing in a fresh snowball, strolling to the meditation room or chapel, sporting a classic Wisconsin Packer’s fan cheesehead throughout the hospital, doing yoga in his room, and creating a root beer taste test challenge for family, patients, and staff.

Optimism was high when the call came of a viable donor for transplant. Interestingly, he was transplanted on national sibling day of 2015. The stars seemed to all align but with that, stress among the family also heightened. My mother was the last one to say good-bye to him before going to the operating room pre transplant. She was looking at him as if it was her baby some 45 years earlier going to his first surgery. He knew my mom and ability to get lost and told her that “God has His plan,” she needed to stop, and say good-bye for now.

With this, instinctively, my nursing brain went back into action and I didn’t suppress it because the risks were so high and I needed answers to process this next phase and keep the family calm and updated. How would his body tolerate the new organ? Would he have to return to the operating room and how often? Would he be comfortable and when would he wake up to see me again? Would complications of bleeding, acidosis, and arrhythmias be manageable? What untoward complications might arise? Would he survive this moment, hour, day, or week? Would he make it out of the hospital alive? How were my parents going to cope? How was I going to keep the family updated practically and in simple terms to positively cope with such a difficult health issue?

Outcomes

Eight themes or key factors of resilience emerged throughout interviews
**Family support**

**Spiritual support**

**Family financial stability**

**Quality health care**

**Strong work ethic**

**Humor**

**Focus on quality of life and normalcy**

**Drive for adventure, pushing boundaries, and new life experiences**

### Adult sibling summary

**First born (1966):** The first born married out of high school and started a family with two beautiful young daughters and is a grandfather of three children. Carrying on my father’s trade as a master electrician, he is employed in a local paper mill. He recently lost his long time wife to Acute Myeloid Leukemia secondary to breast cancer treatment in 2015 at the age of forty-eight. The grief and loss for my eldest brother this past year has been incredibly significant with the loss of his brother and wife within a 4 month time period.

**Second born (1968):** Second born was CHD married shortly after college graduation and has four lovely children. Choosing a career in electrical engineering, is married, and employed in Illinois. His job is a senior level job requiring world travel commitments. For an extended period of time he relocated to Denmark. While there, my mother spent time visiting and enjoying her first ever European holiday.

**Third born (1970):** A nursing career was envisioned in high school for the third born. After discussions with mentors, and parents, I gained experience employed as a certified nursing assistant学校的三年级。在讨论了导师和父母后，我获得了经验，作为为期一年的医疗中心的认证护理助理，我确实厌倦了每家公司的工作。我看到一些人现在认为“这个孩子没有活着的希望”……所以有时候我更努力更快了，但是我没有停止参加……我看到一些人认为那将使他们与他们的特殊需要的孩子隔离，保护他们免受一切……这个孩子没有希望过上正常的生活”。

**Fourth born (1973):** The fourth born chose a career in electrical engineering, is married, and employed in Illinois. His job is a senior level job requiring world travel commitments. For an extended period of time he relocated to Denmark. While there, my mother spent time visiting and enjoying her first ever European holiday.

**Adult milestone June 2014.**

The fourth born chose a career in electrical engineering, is married, and employed in Illinois. His job is a senior level job requiring world travel commitments. For an extended period of time he relocated to Denmark. While there, my mother spent time visiting and enjoying her first ever European holiday.

**Quote from my brother on activity intolerance (November 20, 2014):**

“I think one of the best things Mom and Dad did was treat me as normal as any of you guys (3 siblings)...I knew I tired more quickly, but that didn’t stop me from participating...I see some people now that will almost isolate their special needs child and protect them from anything and everything...that child has no hope of living a normal life”.

A pediatric career began at the local children’s hospital in the pediatric oncology and transplant unit. Transferring to the pediatric intensive care unit, my drive to pursue an advanced degree in nursing was initiated. Following graduation in 1999, I began my pediatric nurse practitioner (PNP) career in a full-time role in pediatric cardiology. Teamwork, advancing clinical skills, autonomy, and professional development were modeled by mentors in this new and developing role. Educational tools for parents, nutritional support protocols, and professional development were modeled by mentors in this new and developing role. Educational tools for parents, nutritional support development, and research were career achievements. The home surveillance monitoring program (HMP) was developed for high risk interstage time period for CHD between stage 1 and stage 2 palliation utilizing a home scale, pulse oximeter, binder, and close interstage clinical management [25]. In addition, the Fontan protocol for postoperative persistent chest tube drainage was developed [26].

In 2007, my spouse’s job relocated our family to New England. There my career took on further development at the world renowned pediatric cardiovascular surgery center from 2008-2013. During
this time, a full-time position was not the best work life balance for our family. A part-time PNP position in a high volume surgical and referral center was undertaken. In addition to my role on the ward, I collaborated on parent educational tools, facilitated transferring the Wisconsin born HMP into a large institution [27,28], presented at the American Heart Association annual conference [29], and participated with the local team for the National Pediatric Cardiology Quality Improvement Collaborative [30,31]. Family, work, life balance was disrupted near the end of my career in New England. Anxiety, depression, nursing burnout, and professional compassion fatigue arose in 2012. This was treated with the help of a primary internal medical specialist, mental health support, and Bikram yoga.

In 2013, our family relocated back to the Midwest due to my husband’s job advancement. Primary focus during this transition time was on my nuclear family (husband, daughter, and son), extended family, self-care, and volunteering. My daughter was finishing her final year at a new high school and son entering middle school. One year later in the fall of 2014, my brother was chronically hospitalized awaiting heart transplant. Regular visits to support quality of life were important to continue our sibling relationship. My daughter continued her relationship with her uncle by attending many of these visits. My daughter is now a sophomore in college with an interest in the life science space. My son is finishing up eighth grade and active in extracurricular sports and music activities. Both are thriving.

As part of my CHD healing journey, I recently attended the advocacy conference with my 70 year old mother in Washington, DC. Collaborating with leaders in the field of CHD, we told our family’s story and advocated in February of 2016 with our local congressman for increased awareness of CHD, support for quality treatment options, and research for the number one birth defect [32,33]. The Centers for Disease Control and National Institutes of Health also support the cause. This effort cannot be done in isolation. Please read about the re-authorization act put forward in November of 2015, reach out to your congressman, and keep CHD present and visible.

Reflecting on my experiences with CHD over a lifetime, my brother, family, and countless other CHD families that have touched my life have reinforced and taught me valuable insights about the importance of striving for normalcy. There are more supports and resources often required [34], but life is not defined by the disease. Life with CHD can be complicated, frustrating, and unfair. It also can be fulfilling, rewarding, and demonstrate to others the value of making the most of the precious gift we are all given.

Discussion

This case study provides one example of a healthy sibling’s perspective on the family growing up with CHD. Hope, positive outlook, surgical advancement, and medical support within the health care profession were present through nearly five decades of life in addition to typical normal developmental milestones. Never was my brother lost to medical follow up in his lifetime. Learning about the impact of CHD on my brother and our family system was not a choice. Burdens in care (financial and otherwise) were present throughout the lifespan. Essential components of resilience in our family included extended family support, spiritual support, family financial stability, quality health care, strong work ethic, humor, focus on quality of life and normalcy, and drive for adventure including pushing boundaries toward new life experiences. Ultimately adult milestones and successful contributions to the community at large were achieved for all four siblings.

Supporting sibling’s understanding of CHD throughout the developmental spectrum is important to demystify the disease, treatment, and grief process. In my lifetime alone, more focus is being given to this need through child life specialists. The entrance of the hospital where my brother was treated for a large part of his lifetime now contains a sibling care room [35]. Within the last two years alone, discussions with health professional colleagues and expert parents in CHD have been increasingly positive that sibling presence is not being forgotten as part of the overall assessment of the care plan. I am hopeful that this will continue.

This case highlights the reality of psychological stressors presenting throughout a lifetime for the third in birth order sibling and PNP experienced in CHD. One could speculate that regardless of the presence of CHD, I may have still developed psychological stressors in 2012. Any nurse or health care provider exposed to the fragility of life in a work environment is at risk. A compassionate and empathetic heart, my brother’s fragility in infancy, and nursing experience with consistent life and death exposure in the Intersstage period likely played a role in the development of compassion fatigue and burnout. Without proper treatment at that time, I may have encountered additional challenges dealing with the significant health crisis and ultimate death of my brother a few years later. I am forever grateful for the resources present within my family and health care team to address, treat, and manage the issue and move towards a healthier today and tomorrow.

Conclusion

Changing population of CHD

CHD care has evolved greatly in the last several decades yet remains common, costly, serious, and bears no cure. Medical advances and better outcomes have continued to show promise. Children today that are diagnosed with single ventricle disease undergo the Fontan operation at much earlier time point than my brother, typically 2-4 years of age. Fetal intervention is a possibility for some lesions [36]. With fetal diagnosis, parents and their families are impacted by the transition of a new member into the family and the complexities of a critical health issue that must be addressed early in life [37]. In essence, they are trying to navigate the “emotional tightrope” of caregiving and parental transitions [38]. By clustering the medical and surgical treatments earlier in time, there is increased frequency of disruption within the family system, burden of health and technology costs, stress, and depletion of family resources.

Stress in terms of finances, emotional drain, and family member burden are reported in the literature [39-41]. Based on practical experience over greater than 20 years of nursing experience, the CHD
families of today comprise a mixture of dual income households with more financial health care coverage concerns and often less extended family in close proximity. This can impact a family’s ability to positively engage in care and cope positively to these variables, particularly those with limited resources at baseline (i.e. single parent, lack of extended family support, lower socioeconomic, poverty, non-English speaking or language barrier, or another sibling with chronic health needs).

**Promoting healthy families for the future**

Realistic hope and faith for a positive medical outcome must be preserved in addition to preparation for an unforeseen fatal outcome. When a patient is lost due to CHD and/or co-morbidity factors, the significant death is palpable for the entire family, particularly when nearly five decades of life experiences are shared. Moving through the grief and loss is a challenging and ongoing process for all. As an adult sibling experiencing a loss of my brother, the commonly termed “forgotten griever” persisted throughout my grief, loss, and mourning. Current research is slowly growing in the area of adult sibling bereavement [42]. Focusing on a new way to live in the present moment without forgetting those left behind is critical to maintaining overall health of all family impacted by CHD, (whether sibling, mother, father, wife, son, daughter, aunt, uncle, or other significant relationship). Bereavement programs need to be reevaluated as part of the future to provide developmental supports for all ages impacted by CHD, particularly with a growing population of adult congenital heart disease patients.

This case study represents one opportunity to understand the complexities of a sibling relationship (and family) and developmental milestones throughout four decades as it relates to CHD. While retrospective and not generalizable, it offers a nursing and sibling point of view into one nuclear family’s experience navigating a complex CHD diagnosis throughout a lifetime. Countless other untold personal sibling journeys need to be told and heard in this growing population of families impacted by CHD. Providing qualitative and prospective research studies with larger sample sizes (including patients, parents, siblings, and grandparents) and longer assessment time spans is essential for future research. With this fundamental next step, issues can be identified in a timely fashion, assessed, and treated with the focus on the goal of a healthier future for all those impacted by CHD.

Maintaining healthy lifestyle goals including mind, body, and spirit is critical in lieu of the additional life-threatening stresses CHD families encounter. Fostering and modeling resiliency in families with a dynamic and ever changing treatment plans is important. Whenever possible, care plans need to engage and be mindful of these healthy lifestyle goals, de-intensify fears, provide practical action plans, encourage resources for support, and focus on normalcy. Nonjudgmental assessment and intervention of current issues must occur by all team members (family, primary care provider, nursing, cardiologist, surgeon, subspecialty, etc.) regardless of the issue. Psychosocial issues such as anxiety, depression, compassion fatigue, and caregiver burnout are not a sign of weakness. Increased education, support, and awareness for patients, families, and providers are necessary to providing prompt assessment and intervention.

Striving for normal developmental milestones throughout a lifetime such as a second birthday, starting kindergarten, graduating high school, graduating college, marrying, pursing an active career, and starting a family must continue to be celebrated and cherished. With the complexities and uncertainties involved with living life surrounded by CHD, these milestones often require more steps to achieve. The accomplishment and pride associated with the achievement is priceless.
