Topical Phytotherapy is the Nobel Approach for Revision of Total Knee Replacement: A Unique Case Study

Abstract

Knee-osteoarthritis (KOA) can only be treated by total knee replacement (TKR), which is a well-known surgical intervention in the globe. But in some cases, TKR failed in the operated knee-joint as well as non-operated knee-joint may pose risk of KOA. In general, patients are advised to undergo revision of TKR when two prostheses of femoral and tibial compartments are prolapsed or loosen or such other reasons as well as non-operating knee-joint needs to be operated urgently. The phytotherapy with Indian medicinal plants are well-established. The present case study was aimed to determine the efficacy of topical phytotherapeutic treatment for 90 days in order to prevent the revision of TKR, improve the pain and functional performance in daily activities in four Indian patients. After 90 days of topical phytotherapy treatment, the results were observed a significant decrease in pain in both the legs and lower back under visual analogue scale (p<0.05), improvement of pain (p<0.05), stiffness (p<0.05) and physical function (p<0.05) under WOMAC Index, a significant improvement in the Karnofsky scale (<0.05), reduction of obesity confirmed by body mass index (p<0.05) and normal radiological features. In conclusion, failed TKR can be treated by phytotherapy without further revision evidenced by normalization of above-mentioned parameters.

Introduction

Total knee replacement (TKR) is a common and ultimate treatment of knee osteoarthritis (KOA) in India and other parts of the globe. Basically, the concept of TKR is mainly to relief pain and improvement of performance in daily activities [1,2]. However, TKR is done on the basis of different prostheses design such as cruciate retaining, posterior stabilized and high flexion posterior stabilized prostheses [2-6]. According to Julian J et al. there is a risk of prosthesis failure in young age groups of <55 years old due to infection, obesity, physical activity, loosening, osteolysis, etc. and needs revision for further prosthesis [7-9]. In an earlier study, surgical outcome revealed dissatisfaction in patients [10]. In the present report, it was aimed to detect efficacy of topical phytotherapeutic treatment for preventing the revision of TKR with normalization of daily functional activities without pain, reduction of body weights and also improved the damaged knee-joints in four Indian patients.

Case Study

Four female patients aged 65, 73, 55 and 64 years old respectively advised to further revision of unilateral TKR because they suffered with severe pain on weight-bearing, impaired function, and limitations of daily activities. They were treated at OPTM Healthcare (P) Ltd., India, from January 2016 to July 2016. The study protocol was evaluated and approved by the OPTM Research Institute Ethics Committee. An institutional review board-approved consent form for physical examinations or treatments for diminishing pain or inflammation, for muscle relaxation, or to improve of the skeletal muscles during the last four weeks prior to the treatment of 90 days. The radiological features were observed bone erosion and revision for further prosthesis needed in the post-operated knee joint and required surgical intervention in the non-surgical knee joint as the patients were suffering with severe pain, stiffness and physical functional disabilities in both the knee-joints (Table 1) (Figures 1A,1B, 2A,2B,3A,3B,4A and 4B). Four pair of radiological images (before and after) is depicted in Figures 1-4.

Different types of prostheses in the tibia compartment have been used during TKR in order to get successful results but in the present report of the four patients have shown the further revision of TKR required and have risk of secondary knee osteoarthritis and non-operated knee-joint needs surgical intervention as shown in Figures 1A,1B,2A,2B,3A,3B,4A and 4B. All the four patients decided not to go for surgery. Hence, author has taken as challenge to recover them with the help of topical phytotherapeutic treatment protocol.

patients were not being treated by oral medications; injections; massage with any type of herbal gels; and any type of alternative interventions or treatments for diminishing pain or inflammation, for muscle relaxation, or to improve of the skeletal muscles during the last four weeks prior to the treatment of 90 days. The radiological features were observed bone erosion and revision for further prosthesis needed in the post-operated knee joint and required surgical intervention in the non-surgical knee joint as the patients were suffering with severe pain, stiffness and physical functional disabilities in both the knee-joints (Table 1) (Figures 1A,1B, 2A,2B,3A,3B,4A and 4B). Four pair of radiological images (before and after) is depicted in Figures 1-4.

Different types of prostheses in the tibia compartment have been used during TKR in order to get successful results but in the present report of the four patients have shown the further revision of TKR required and have risk of secondary knee osteoarthritis and non-operated knee-joint needs surgical intervention as shown in Figures 1A,1B,2A,2B,3A,3B,4A and 4B. All the four patients decided not to go for surgery. Hence, author has taken as challenge to recover them with the help of topical phytotherapeutic treatment protocol.
The main objectives of the treatment are: to reduce pain, inflammation and stiffness of muscles without dependence upon any types of pain killers or corticosteroid injection or arthrocentesis; to increase the muscular strength without using supporting belt on the waist or knee joints and the gaps between the bones/vertebrae; to rectify calcifications/degeneration of bones, and to normalize the varus/valgus deformities (Figures 1-4) [10-12].

Several researchers had already reported the medical effects (specially on pain, inflammation and stiffness of muscles) on human body of the phytochemicals contained in Cissus quadrangularis, Heliotropium indicum, Rosemarinus officinalis, Calotropis gigantea, Boswellia serrata and Curcuma longa [14-16,19-23].

Each 30 ml of said viscous phyto-based oil is to be applied with the
tip of three fingers in particular technique over the skin three times a day with minimum interval of time two hours for 90 days; lying in six different postural positions such as supine, prone, right and left contralateral and right and left cross (supper) contralateral in different programmed sequences in order to nourished the effected group of badly damaged muscles and nerves in the legs and lumber regions during KOA [11,13,15,24]. The author had previously discussed elaborately, the reasons of the programmed sequences with six postural positions, and the purpose of special devices such as medicated pad, wooden roller and bet tarry operated electronic nerve stimulator used during the therapy [11,13,24].

The treatment protocol is based on well defined certain principles and theories and also based on the fundamental properties of all muscles such as excitability, conductivity, contractility, elasticity and viscosity with the help of well known chemical, mechanical, thermal and electrical stimuli [11,13,24]. In the phytotherapy protocol, viscous phyto-based oil serves the purpose of producing chemical stimulation, manipulation with the tip of three fingers and Wooden roller develop mechanical stimulation, medicated pads with control temperature generates thermal stimulation and 9 volt DC electronic nerve stimulator produces electrical stimulation [11,24,25].

Tables 2 and 3, summarize the pain and performance parameters of four patients. Patients underwent standing X-ray examination to the most important leg joints and lower back: it confirmed knee involvement with large osteophytes, narrowing the joint space, increased density of the subchondral bone, large subchondral cysts in the non-operated knee joints. The joint spaces of the operated knee joint were completely jointed in case of patients 1 and 3, substantially diminished in case of patient 2 and sticking the long fixed pin at the

improvement of the knee-joints (both non-operated and operated) have also been observed as evidenced by X-ray imaging (Figure 1C,1D,2C,2D,3C,3D,4C and 4D).

**Discussion**

The present case reports indicate the failure in TKR and osteoporosis after TKR with pain and non-performance of daily activities for which alternative treatment with specialised topical phytotherapy for 90 days would be considered to be best. Generally, the TKR supports to relief pain and improvement of performance in daily activities [1,2]. Further revision on TKR may be stressful, risk and expensive but specialized topical phytotherapeutic treatment after 90 days to the studied patients are suitable therapy where substantial improvement in pain, stiffness, functional and performance abilities, BMI with highly statistically significant values (p<0.05), knee gaps, osteoporosis and osteophytes in non-operated knee-joint and knee flexion were observed (Table 3) (Figures 1C,1D,2C,2D,3C,3D,4C,4D,5 and 6).

**Conclusion**

The aim of the TKR is to reduce the pain, increase the functional ability and the gap between the femoral and tibial compartments. The present study firmly confirmed with normalization of prolapsed prostheses by increasing the gap between the compartments of the operated and non-operated knee-joints as evidenced by X-ray images and diminishing pain, stiffness and improvement of physical functional and performance abilities and reduction of inflammation as well as obesity confirmed by BMI with the help of topical phytotherapeutic method within 90 days (Table 3) (Figures 1C,1D,2C,2D,3C,3D,4C,4D,5 and 6).

Further researches should be undertaken on:

1. Deranged anatomical and abnormal biochemical features after TKR,
2. Phytochemicals characterization by using Mass Spectroscopy,
3. Measurements of collagen and 4-hydroxyproline (O-Hyp) to show collagen formation, which takes place with the treatment, and
4. Measurements of hyaluronic acid both in volume and chemical compositions before and after the treatment to detect how the phytochemicals changing the chemical compositions of hyaluronic acid.
